

# PRISM: PRime degree ISogeny Mechanism

Isogeny Club #5.5

Riccardo Invernizzi

COSIC - KU Leuven

December 3rd

# Outline

1. Main Idea
2. How to Do It
3. Security and attacks
4. Other isogeny based signatures
5. Implementation and Performance

## Credits

- ▶ Andrea Basso
- ▶ Giacomo Borin
- ▶ Wouter Castryck
- ▶ Maria Corte-Real Santos
- ▶ Riccardo Invernizzi (Me)
- ▶ Luciano Maino
- ▶ Antonin Leroux
- ▶ Frederik Vercauteren
- ▶ Benjamin Wesolowski

## High degree isogenies

Main idea: computing high (prime) degree isogenies is

- ▶ **hard** without knowledge of the endomorphism ring
  - best way: work rationally
  - exponential in the smallest factor
- ▶ **easy** with it
  - look at the corresponding ideals

This is exactly what we want in crypto.

## Identification Protocol

- ▶ Verification key: random curve  $E_{vk}$
- ▶ secret key:  $I_{sk}, \text{End}(E_{vk})$
- ▶ query: a big prime number  $q$
- ▶ response: a degree  $q(2^a - q)$  isogeny starting from  $E_{vk}$
- ▶ verification: evaluate the isogeny and check the degree

## Signature Scheme

- ▶ Public key: random curve  $E_{vk}$
- ▶ secret key:  $I_{sk}, \text{End}(E_{vk})$
- ▶ *query: hash the message  $m$  into a prime number  $q$*
- ▶ signature: a degree  $q(2^a - q)$  isogeny starting from  $E_{vk}$
- ▶ verification: evaluate the isogeny and check the degree

# Outline

1. Main Idea
2. How to Do It
3. Security and attacks
4. Other isogeny based signatures
5. Implementation and Performance

## Secret Key

- ▶ Start from  $E_0$
- ▶ heuristic key-generation (QFESTA)
  - endomorphism of degree  $n(2^a - n)$
  - isogeny factorization
- ▶ rigorous key-generation (SQISign2D-West)
  - uniformly random ideal
  - IdealToIsogeny
- ▶ any other idea to obtain a known EndRing curve without consuming 2-torsion.

## Response

- ▶ Generate an  $\mathcal{O}_0$ -ideal  $I_{chall}$  of norm  $q(2^a - q)$ 
  - `RandomFixedNormIdeal`
- ▶ compute  $I_\sigma = [I_{sk}] * I_{chall}$
- ▶ translate  $I_\sigma I_{sk}$  into the corresp. isogeny
  - `IdealToIsogeny`
- ▶ recover  $\sigma$
- ▶ given  $\langle P_{vk}, Q_{vk} \rangle = E_{vk}[2^a]$  compute  $\sigma(P_{vk}), \sigma(Q_{vk})$
- ▶ send  $P_{sig} = [q^{-1}]\sigma(P_{vk}), Q_{sig} = [q^{-1}]\sigma(Q_{vk})$

## Ideal to Isogeny

Main idea:

- ▶ given an ideal  $I$  find ideals  $I_1, I_2$  and integers  $u, v$  s.t.

$$d_1 u + d_2 v = 2^a$$

- ▶ use  $I_1, I_2$  to build a Kani square and recover  $I$ .

We can use it as a black box. But:

- ▶ we need  $p = f2^e - 1$  with  $f$  small cofactor
- ▶ we can reuse SQISign2D-West parameters
- ▶ better keep things odd

## Hash to Prime

- ▶ Take any cryptographic hash function  $H_a : \{0, 1\}^* \rightarrow (2^{a-1}, 2^a)$
- ▶ compute  $H_a(E_{vk} || \text{msg} || \text{counter})$
- ▶ increment counter until a prime is found

Remarks:

- ▶ expected hits:  $1/a$
- ▶ each hash computation requires a primality testing ( $O(a^2)$ )
- ▶ counter can be attached to the signature

## Verification

- ▶ Recover  $q$  from the message (and counter)
- ▶ compute the isogeny with kernel

$$\langle (P_{vk}, P_{sig}), (Q_{vk}, Q_{sig}) \rangle$$

- ▶ obtain an isogeny  $\Phi$  that embeds (factors of)  $\sigma$
- ▶ compute  $(P', -) = \Phi((P_{vk}, 0))$  and  $(Q', -) = \Phi((Q_{vk}, 0))$
- ▶ verify that

$$e_{2^a}(P', Q') = e_{2^a}(P_{vk}, Q_{vk})^n$$

with  $n \in \{q, 2^a - q\}$

# Outline

1. Main Idea
2. How to Do It
3. Security and attacks
4. Other isogeny based signatures
5. Implementation and Performance

## High degree isogeny oracles

- ▶ Many schemes (SQISign-HD...) rely on isogeny oracles
- ▶ hard to argue security without
- ▶ there is no known way to compute them
- ▶ claimed to leak no information
  - smooth isogenies cover the isogeny graph
  - for every given rough isogeny, there is an equivalent smooth one
- ▶ *security by common belief*

## Key Recovery

- ▶ Recovering the secret key means computing  $\text{End}(E_{vk})$
- ▶  $E_{vk}$  is a random curve
- ▶ best known algorithms: Delfs-Galbraith & friends,  $\tilde{O}(p^{1/2})$
- ▶ requires  $p \approx 2\lambda$

## Forgery and impersonation

- ▶ *Main problem*: given a prime  $q$  compute a degree  $q(2^a - q)$  isogeny from a given curve  $E_{vk}$
- ▶ best way: *Velu-sqrt*
  - computes the isogeny in  $O(q^{1/2})$
  - but: requires available  $q$ -torsion in  $O(q)$
  - total complexity  $O(q^{3/2})$
- ▶ other ways (kernel polynomial, ...) are even slower
- ▶ implies  $q > 2^{2\lambda/3}$  so  $a > 2\lambda/3$  (already ok)
- ▶ means  $a \approx 90$  bits for Level 1

## Reusing a signature

- ▶ Can always reuse part of a signature (e.g. factors of  $2^a - q$ )
  - choosing  $q > 2^{a-1}$  prime prevents it
- ▶ does looking at signatures help? *Hopefully not*
  - can already compute high degree isogenies from  $E_{vk}$
  - being *prime degree* is most likely a disadvantage

# Hashing

- ▶ Another attack: *hash collisions*
- ▶ we hash into primes but the hash is repeated
  - the image space for the hash is only  $2^\lambda/\lambda$
  - each message needs  $\lambda$  hash (+ primality tests)
- ▶  $a \approx 2\lambda$  is enough
- ▶ can do slightly better (e.g.  $a = 219$  for  $\lambda = 128$ )
- ▶ by far the biggest constraint on  $a$

# Outline

1. Main Idea
2. How to Do It
3. Security and attacks
4. Other isogeny based signatures
5. Implementation and Performance

## The SQIsign Family

A different paradigm from the SQIsign family

- ▶ no Fiat-Shamir
- ▶ *hash & sign*
- ▶ more flexible (Erebor and Durian...)
- ▶ comparable size and speed

## Other prime-degree isogeny signatures

Not really *the first* prime-degree isogeny based signature

- ▶ DeuringVRF
- ▶ SQIPrime

## Deuring VRF idea

- ▶ Pick  $d$  prime
- ▶  $P, Q$  basis of  $E[d]$
- ▶  $\iota \in \text{End}(E)$  s.t.  $\iota(P) = Q$
- ▶  $I_P$  the ideal corresponding to  $\langle P \rangle$
- ▶ ideal of  $\langle P + kQ \rangle$  is easy to compute
- ▶ evaluate with the IdealToIsogeny machinery

## DeuringVRF-based protocols

Then in practice

- ▶ in DeuringVRF,  $k$  is the input
  - the random output is the codomain of the isogeny
- ▶ in SQIPrime,  $k$  is the challenge
  - evaluation by completing the diagram
  - verifier cannot compute the challenge

## Comparison

- ▶ setting: fixed prime (VRF) vs. different primes (PRISM)
- ▶ consequence:  $d|(p+1)$  with  $d$  big prime
- ▶ bigger cofactor on  $p$  impacts IdealToIsogeny
- ▶ hash & sign and verification are similar
- ▶ overall PRISM is faster than VRF in all steps
- ▶ SQIPrime: VRF setting but different protocol

# Outline

1. Main Idea
2. How to Do It
3. Security and attacks
4. Other isogeny based signatures
5. Implementation and Performance

## Public key size

- ▶  $E_{vk}$ :  $4\lambda$  bits
- ▶ Deterministic basis of  $E_{vk}[2^a]$ 
  - included (fast) or computed (compact)
  - tradeoff: hints (SQISign2D-West)

## Signature Sizes

Standard method:

- ▶ codomain  $E_{sig}$ :  $4\lambda$  bits
- ▶ kernel  $(P_{sig}, Q_{sig})$ :  $16\lambda$  bits ( $8\lambda$  per point)
- ▶ deterministic basis: 2 coefficients per point
- ▶  $a \approx 2\lambda$ , so  $2\lambda$  bits per coefficient
- ▶  $12\lambda$  bits in total
- ▶ det. basis + point compression:  $11\lambda$  bits in total

## Signature Sizes

Instead:

- ▶ send  $P_{sig}$ :  $8\lambda$  bits
- ▶ recover  $E_{sig}$  (one field inversion)
- ▶ send  $x(Q_{sig})$  ( $4\lambda$  bits) + one bit (and one square root)
- ▶ no det. basis or pairings
- ▶  $12\lambda$  bits but much faster

## Signature Sizes - Comparison

Protocol	<b>This Work</b>	SQIsign	SQIsign2D-East	SQIsign2D-West	SQIPrime
Sig. size (bits)	$12\lambda$	$\approx 11\lambda$	$12\lambda$	$9\lambda$	$19\lambda$

- ▶ SQISign2D-East: can go to  $10\lambda$  at the cost of more 2D steps
- ▶ SQISign2D-West: can go to  $8\lambda$  at the cost of pairings
- ▶ SQIPrime: can go to  $12\lambda$  using 4D isogenies

## Communication cost

- ▶ Only require  $a \approx \lambda + \log \lambda$
- ▶ curve:  $4\lambda$  bits
- ▶ points:  $4a \approx 4\lambda + 4 \log \lambda$  (+ det. basis)
- ▶ compressed points:  $3a \approx 3\lambda + 3 \log \lambda$  (+ pairings)
- ▶ total:  $8\lambda + 4 \log \lambda$  /  $7\lambda + 3 \log \lambda$

## Performance

Protocol		Type of isogeny				
		2	3	5	(2, 2)	(2, 2, 2, 2)
<b>This Work</b>	KeyGen	-	-	-	496	-
	Sign	-	-	-	496	-
	Verify	-	-	-	219	-
SQIsignHD	KeyGen	378	234	-	-	-
	Sign	252	312	-	-	-
	Verify	-	78	-	-	142
SQIsign2D-West	KeyGen	-	-	-	496	-
	Sign	(248)	-	-	992	-
	Verify	(248)	-	-	(126)	-
SQIsign2D-West (Heuristic)	KeyGen	-	-	-	496	-
	Sign	(122)	-	-	624	-
	Verify	(122)	-	-	(126)	-
SQIsign2D-East	KeyGen	-	-	-	253	-
	Sign	127	(2)	(1)	641	-
	Verify	127	(2)	(1)	129	-

## Performance - Comparison

- ▶ Key generation is the same
- ▶ no commitment / challenge isogenies
- ▶ hash to prime (signing) but no det. basis (verification)
- ▶ PRISM-id verification twice as fast:
  - only need  $a$  2D isogenies
  - $a = 135$  for NIST Level 1

## Performance - Comparison

	KeyGen	77.4
SQISign2D-West	Sign	285.7
	Verify	11.9
	KeyGen	78.2
This work	Sign	157.6
	Verify	16.9

- ▶ Implemented on the SQISign2D-West codebase
- ▶ signing  $1.8\times$  faster, verification  $1.4\times$  slower
- ▶ currently: unoptimized LLL takes 40% of the time
- ▶ other schemes: not implemented but we can estimate

## Conclusions

- ▶ Totally different idea from traditional schemes
- ▶ Competitive performance / size
- ▶ More flexible

Thank you for your attention.
